arXiv:1403.1710v2 [hep-ph] 20 Mar 2014

We study a light dark matter in a radiative neutrino model to explain the X-ray line signal at about 3.5 keV recently reported by XMN-Newton X-ray observatory using data of various galaxy clusters and Andromeda galaxy. The signal requires very tiny mixing between the dark matter and an active neutrino; $\sin^2 2\theta \approx 10^{-10}$. It could suggest that such a light dark matter cannot contribute to the observed neutrino masses if we use the seesaw mechanism. In other words, neutrino masses might come a structure different from the dark matter. We propose a model in which Dirac type active neutrino masses are induced at one-loop level. On the other hand the mixing between active neutrino and dark matter are generated at two-loop level. As a result we can explain both the observed neutrino masses and the X-ray line signal from the dark matter decay with rather mild hierarchy of parameters in TeV scale.

I. INTRODUCTION

The energy density of dark matter (DM) occupies about 27 % of the universe. However, its nature is not known yet clearly. Recently two groups independently reported anomalous X-ray line signal at about 3.5 keV from the analysis of XMN-Newton X-ray observatory data of various galaxy clusters and Andromeda galaxy [1, 2]. In this sense, the X-ray line signal at 3.5 keV can be explained by a 7 keV dark matter mixing with the active neutrino by angle given by $\sin^2 2\theta \approx 10^{-10}$. This could provide a lot of implications on the nature of DM. Already several works have appeared in various models [3–11]. Due to its too small mixing, the DM cannot contribute to the neutrino masses directly.

In this letter, we propose a Dirac type neutrino scenario at one-loop level, introducing continuous $U(1)'$ symmetry [12–14]. On the other hand the mixing between active neutrino and dark matter are generated at two-loop level. As a result, such a tiny mixing can be naturally explained within TeV scale.

This paper is organized as follows. In Sec. II, we show our model for neutrino sector and DM sector, and analyze these properties. In Sec. III, we summarize and conclude.

II. THE MODEL

A. Model setup

Particle	L_L	e_R	S_L	S_R	N_R	X
$(SU(2)_L, U(1)_Y)$	$(\mathbf{2}, -1/2)$	$(\mathbf{1}, -1)$	$(\mathbf{1}, 0)$	$(\mathbf{1}, 0)$	$(\mathbf{1}, 0)$	$(\mathbf{1}, 0)$
$U(1)'$	$-(3\Sigma + \Sigma')/4$	$-(3\Sigma + \Sigma')/4$	$(3\Sigma - \Sigma')/4$	$(3\Sigma - \Sigma')/4$	$(5\Sigma - \Sigma')/4$	$3(-\Sigma + \Sigma')/4$

TABLE I: The particle contents and the charges for fermions.

Particle	η	Φ	χ_1	χ_2	χ_3	Σ	Σ'
$(SU(2)_L, U(1)_Y)$	$(\mathbf{2}, 1/2)$	$(\mathbf{2}, 1/2)$	$(\mathbf{1}, 0)$	$(\mathbf{1}, 0)$	$(\mathbf{1}, 0)$	$(\mathbf{1}, 0)$	$(\mathbf{1}, 0)$
$U(1)'$	$3\Sigma/2$	0	$-\Sigma/2$	$-\Sigma'/2$	$-(3\Sigma - \Sigma')/2$	Σ	Σ'

TABLE II: The particle contents and the charges for bosons.

We discuss a one-loop induced radiative neutrino model. The particle contents are shown in Tab. I and Tab. II. Here one finds that all the terms are written in terms of the charges of Σ and Σ', as can be seen in those tables.[1] We add three $SU(2)_L$ singlet vector like neutral fermions S_L and S_R, three singlet Dirac fermions N_R, and gauge singlet Majorana fermion X, which is expected to be DM. For new bosons, we introduce $SU(2)_L$ doublet scalar η and singlet scalars χ_1, χ_2, χ_3, Σ, and Σ' to the standard model (SM). We suppose that only the SM-like Higgs Φ, Σ, and Σ' have vacuum expectation values (VEVs), $v/\sqrt{2}$, $v_\Sigma/\sqrt{2}$, and $v_{\Sigma'}/\sqrt{2}$, respectively, where $v = 246$ GeV and $\mathcal{O}(10)$ keV $= v_{\Sigma'} < v_\Sigma \ll v$ is assumed.

The continuous $U(1)'$ symmetry is imposed so as to restrict their interaction adequately. Here notice that $\Sigma + \Sigma' \neq 0$ to forbid the mass term of $N_R X$ that provides too large enhancement of the mixing between active neutrinos and X.

Moreover, we impose to generate mass term of X through VEV of Σ' for our convenience. From this $\Sigma = 5\Sigma'/3$ is derived.

The renormalizable Lagrangian for Yukawa sector and relevant scalar potential under these assignments are given by

$$-\mathcal{L}_Y = y_\ell \bar{L}_L \Phi e_R + y_\eta \bar{L}_L \eta^* S_R + y_{\chi_1} \bar{S}_L N_R \chi_1 + y_{\chi_2} \bar{S}_R^c X \chi_2 + y_{\chi_3} \bar{S}_R^c S_R \chi_3 + \text{h.c.} \quad \text{(II.1)}$$

$$+ \mu_1 \Sigma (\chi_1)^2 + \mu_2 \Sigma' (\chi_2)^2 + a(\Phi^\dagger \eta)\chi_1 \Sigma^* + b(\Phi^\dagger \eta)\chi_2 \chi_3 + M_S \bar{S}_L S_R + \lambda \Sigma' X X + \text{(II.2)}$$

where the first term of $\mathcal{L}_Y$ can generates the charged-lepton masses, and all the couplings are assumed to be real. Moreover there is a mixing between η and χ_1, but χ_2 and χ_3 are mass eigenstate from the beginning. The χ_2 has a mass splitting between real part and imaginary part as follows: $m_{\chi_{2_R}} = \sqrt{m_{\chi_{2_I}}^2 + 2\sqrt{2}\mu_2 v_{\Sigma'}}$, that plays an crucial role in generating non vanishing neutrino mass as well as mixing active neutrino and DM as discussed later.

After the scalar fields get vev's, (II.2) suggests there is a remnant Z_2 symmetry. The odd particles under this discrete symmetry is $L_L, e_R, N_R, X, \eta, \chi_1, \chi_2$. The lightest Z_2-odd particle is the lightest neutrino and X can decay into it without breaking Z_2 symmetry.

[1] We used the same notation, Σ, Σ', both for the fields and their $U(1)'$ charges for simplicity.

B. Neutrino mass matrix

The Dirac neutrino mass matrix at one-loop level as depicted in the left hand side of Fig. 1 is given by [15]

$$(m_\nu)_{ab} = \sum_{\alpha=1}^{3} \left\{ \frac{M_{S\alpha}}{64\pi^2} (y_\eta)_{a\alpha} (y_{\chi_1})_{b\alpha} \sin 2\theta_R I\left(\frac{m^2_{H_{\chi_1}}}{M^2_{S\alpha}}, \frac{m^2_{H_\eta}}{M^2_{S\alpha}} \right) - [(H_{\chi_1}, H_\eta, \theta_R) \to (A_{\chi_1}, A_\eta, \theta_I)] \right\}, \tag{II.3}$$

where

$$I(x,y) = \frac{-x\ln x + y\ln y + xy\ln\frac{x}{y}}{(1-x)(1-y)}, \quad \sin 2\theta_R = -\frac{avv_\Sigma}{m^2_{H_\eta} - m^2_{H_{\chi_1}}}, \sin 2\theta_I = -\frac{avv_\Sigma}{m^2_{A_\eta} - m^2_{A_{\chi_1}}}. \tag{II.4}$$

Here H_i and A_i represents real part and imaginary part of mass eigenstates. We show a benchmark point to satisty the data of neutrino masses reported by Planck data [16]; $\sum m_\nu < 0.933$ eV, as follows:

$$\begin{aligned} &a \approx y_\eta y_{\chi_1} \approx 1, \quad m_{H_\eta} \approx 300 \text{ GeV}, \quad m_{H_{\chi_1}} \approx 150 \text{ GeV}, \quad M_S \approx 100 \text{ GeV}, \quad v_\Sigma \approx \mathcal{O}(1) \text{ MeV}, \\ &(m^2_{H_\eta} - m^2_{A_\eta}) \approx (m^2_{H_{\chi_1}} - m^2_{A_{\chi_1}}) \approx \mu_1 v_\Sigma, \quad \sin 2\theta_R \approx \sin 2\theta_I \approx 0.1 (\ll 1). \end{aligned} \tag{II.5}$$

Then we can obtain the neutrino mass as

$$(m_\nu)_{ab} \approx 0.1 \text{ eV}. \tag{II.6}$$

C. Mixing between X and ν

The mixing mass term between X and ν are obtained at two-loop level as depicted in the left hand side of Fig. 1, and its form is given by

$$\begin{aligned} (m_{\nu-X})_{ab} \approx &\sum_{c=1}^{3}\sum_{d=1}^{3} \left[\frac{v(y_\eta)_{ac}(M_S)_c (y_{\chi_3})^*_{cd} (M_S)_d (y_{\chi_2})_{db}}{8\sqrt{2}(4\pi)^4 (M_{Sc})^2} \right] \\ &\times \left[F\left(\frac{m^2_{H_\eta}}{M^2_{Sc}}, \frac{m^2_{\chi_3}}{M^2_{Sc}}, \frac{m^2_{\chi_{2R}}}{M^2_{Sc}} \right) - F\left(\frac{m^2_{H_\eta}}{M^2_{Sc}}, \frac{m^2_{\chi_3}}{M^2_{Sc}}, \frac{m^2_{\chi_{2I}}}{M^2_{Sc}} \right) \right], \end{aligned} \tag{II.7}$$

where we assume $\theta_{RI} \ll 1$, and the loop function F is computed by

$$\begin{aligned} F(X_1, X_2, X_3) = &\int_0^1 dx \int_0^1 dy \int_0^1 dz \delta(x+y+z-1) \int_0^1 d\alpha \int_0^1 d\beta \int_0^1 d\gamma \delta(\alpha+\beta+\gamma-1) \\ &\times \frac{1}{(z^2-z)(\alpha+\beta X_1 - \gamma\Delta)}, \ \Delta = \frac{x\frac{M^2_{Sd}}{M^2_{Sc}} + yX_2 + zX_3}{(z^2-z)}. \end{aligned} \tag{II.8}$$

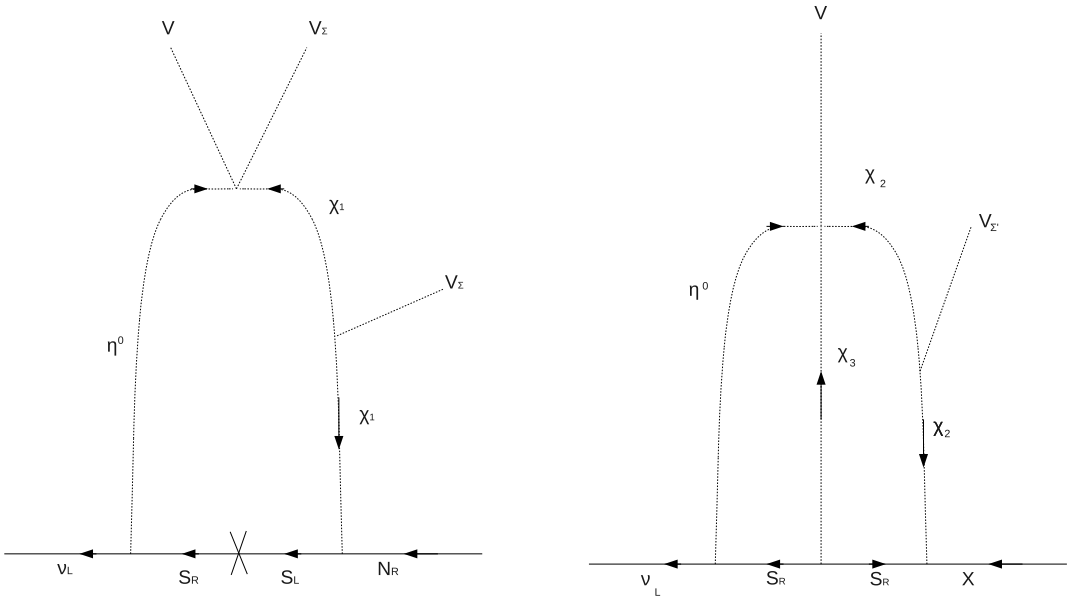

FIG. 1: Diagrams for the Dirac neutrino masses (left) and radiative induced mixing between X and ν (right).

The mixing between active neutrino and DM is given as

$$\theta \equiv \frac{m_{\nu-X}}{m_X} \approx 5 \times 10^{-6}, \tag{II.9}$$

where $m_X = \lambda v_{\Sigma'}/\sqrt{2}(\approx 7.5$ keV) is the mass of DM, and 5×10^{-6} is an expected mixing angle from the X-ray experiment [1, 2]. In Fig. 2 we show the mixing θ as a function of the imaginary mass of χ_2, $m_{\chi_{2I}}$. The figure shows that we can get the required mixing angle near $m_{\chi_{2I}}$ =200 GeV. We fixed $\theta_R \approx \theta_I << 1$, $b(y_\eta y^*_{\chi_3} y_{\chi_2}) \approx 1.0$, M_S =100 GeV, m_{H_η} =300 GeV, m_{χ_3} =200 GeV, μ_2 =1 TeV, and $v_{\Sigma'}$ =10 keV for the figure.

III. SUMMARY AND CONLUSION

We have shown that a light DM in a radiative model can explain the X-ray line signal from the XMN-Newton X-ray observatory data of various galaxy clusters and Andromeda

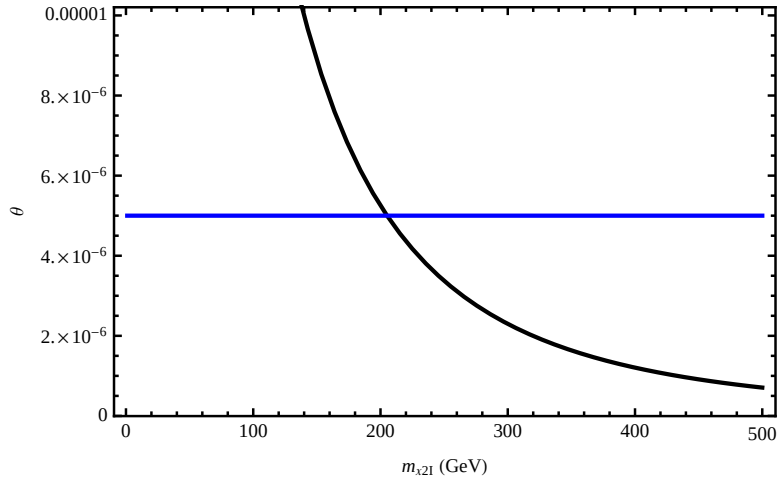

FIG. 2: Order estimation for the mixing angle θ between active neutrino and DM as a function of the χ_{2I} mass. Here we fixed $\theta_R \approx \theta_I \ll 1$, $b(y_\eta y^*_{\chi_3} y_{\chi_2}) \approx 1.0$, M_S =100 GeV, m_{H_η} =300 GeV, m_{χ_3} =200 GeV, μ_2 =1 TeV, and $v_{\Sigma'}$ =10 keV. The black line represents θ given in Eq (II.9). The blue line, $\theta \approx 5 \times 10^{-6}$, is the expected mixing angle to explain X-ray line signal reported by [16].

galaxy . We can accommodate both the observed neutrino masses and the DM ($m_X = 7$ keV) mixing weakly with active neutrino ($\sin^2 2\theta \approx 10^{-10}$) for the signal by a benchmark point with a rather mild hierarchy at TeV scale;

$$a \approx y_\eta y_{\chi_1} \approx 1, \quad m_{H_\eta} \approx 300 \text{ GeV}, \quad m_{H_{\chi_1}} \approx 150 \text{ GeV}, \quad M_S \approx 100 \text{ GeV}, \quad v_\Sigma \approx \mathcal{O}(1) \text{ MeV},$$
$$(m^2_{H_\eta} - m^2_{A_\eta}) \approx (m^2_{H_{\chi_1}} - m^2_{A_{\chi_1}}) \approx \mu_1 v_\Sigma, \quad \sin 2\theta_R \approx \sin 2\theta_I \approx 0.087(<< 1), \quad v_{\Sigma'} = 10 \text{ keV},$$
$$m_{\chi_{2I}} \approx 200 \text{ GeV}, \quad b(y_\eta y^*_{\chi_3} y_{\chi_2}) \approx 1.0, \quad m_{H_\eta} = 300 \text{ GeV}, m_{\chi_3} = 200 \text{ GeV}, \quad \mu_2 = 1 \text{ TeV}. \tag{III.1}$$

The relic density of DM can be thermally obtained through an additional gauged boson, if our $U(1)'$ is localized [17–19], or it can be also obtained non-thermally [20].
